For example, a 12-bit ADC in a 3.3V system has 4,096 distinguishable outputs. Therefore, the resolution of a 12-bit ADC is $3.3/4096 = 0.81\text{mV}$. In an Mbed Enabled system where the digital result from the analog input is in the range of 0.0 to 1.0, a change of 0.81mV in the analog input results in a change in the digital output of $1.0/4096 = 0.00024$.

When using an ADC, for best results, it is important to consider ways to reduce noise. Here are the main things you can to to ensure noise is kept to a minimum when using the mbed Microcontroller : Unused ADC pins are either tied to ground, or declared as DigitalOut Quality of signal source, including low noise design techniques such as filtering.

Analog Input with the mbed The LPC1768, and hence the mbed, has a single 12-bit ADC, with multiplexer. Its voltage reference is the supply voltage, 3.3 V. The available input pins on the mbed are shown opposite, with API utilities below. The ADC output is available in either unsigned binary (as it would be at the ADC output),

There is also an analog watchdog, which can detect if voltage exceed preset threshold values. And of course DMA request based conversions. As LPC1768 works on 3.3 volts, this will be the ADC reference voltage. Now the resolution of ADC = $3.3 / (2^{12}) = 3.3/4096 = 0.000805 = 0.8\text{mV}$.

Designing a system with a 12-bit ADC requires more attention than the lower resolution ADC systems traditionally used in the NXP LPC family of products. As a comparison, using a voltage reference of 3.3 V in a 10-bit ADC system, every converted value differs from the consecutive by 3.2 mV (3.3 V/1024). In the case of a 12-

Discussing the specific design of the ADC system, however, is not necessary for us to understand the concepts of data conversion and implementing the mbed's ADC. 5.1.3 Sampling Frequency. When converting an analog signal to digital, a 'sample' is taken repeatedly and quantized to the accuracy defined by the resolution of the ADC.
